INFORMATION TO USERS

This material was produced from a microfilm copy of the original document. While the most advanced technological means to photograph and reproduce this document have been used, the quality is heavily dependent upon the quality of the original submitted.

The following explanation of techniques is provided to help you understand markings or patterns which may appear on this reproduction.

- 1. The sign or "target" for pages apparently lacking from the document photographed is "Missing Page(s)". If it was possible to obtain the missing page(s) or section, they are spliced into the film along with adjacent pages. This may have necessitated cutting thru an image and duplicating adjacent pages to insure you complete continuity.
- 2. When an image on the film is obliterated with a large round black mark, it is an indication that the photographer suspected that the copy may have moved during exposure and thus cause a blurred image. You will find a good image of the page in the adjacent frame.
- 3. When a map, drawing or chart, etc., was part of the material being photographed the photographer followed a definite method in "sectioning" the material. It is customary to begin photoing at the upper left hand corner of a large sheet and to continue photoing from left to right in equal sections with a small overlap. If necessary, sectioning is continued again beginning below the first row and continuing on until complete.
- 4. The majority of users indicate that the textual content is of greatest value, however, a somewhat higher quality reproduction could be made from "photographs" if essential to the understanding of the dissertation. Silver prints of "photographs" may be ordered at additional charge by writing the Order Department, giving the catalog number, title, author and specific pages you wish reproduced.
- PLEASE NOTE: Some pages may have indistinct print. Filmed as received.

SHORT RANGE ORDER AND DEVELOPMENT OF LONG RANGE ORDER IN NICKEL - 20 ATOMIC PERCENT MOLYBDENUM ALLOY

Approved by:

Dr. E. A. Starke, Jr. Chairman

Dr. E. A. Starke, Jri; Chairman

Dr. Cullis J. sparks

15.0, Tetere

Dr. Bruce G. LeFevre

Date approved by Chairman: Because 21, 1972

ACKNOWLEDGMENTS

The author is deeply indebted to his thesis advisor, Dr. Edgar

A. Starke, for suggesting this research and his constant encouragement
throughout the project.

A very special thanks is extended to Dr. Cullie J Sparks for his tremendous interest in the research and the continued guidance given the author. Without his help much would have remainded undone.

It gives the author great pleasure to thank Dr. Ray A. Young of the Physics Department for allowing the use of the automated diffractometer for this research and Dr. Robin Williams of the Oak Ridge National Laboratory, for performing the simulation runs for the dissertation.

Finally, the author would like to thank Dr. Bruce G. LeFevre for reviewing this work. His interest and criticism is greatly appreciated.

SUMMARY

The short-range ordered structure present in as-quenched Ni₄Mo and the initial development of the long-range-ordered structure has been studied using single crystal x-ray diffuse scattering techniques.

Measurements of the diffuse x-ray intensities were made in a minimum volume in reciprocal space for the fcc alloy, so that quantitative determination of local-order parameters could be made. The "size effect" coefficients for the first and second order displacement effects were separated from those due to local order and their values were determined. The local-order parameters were used for a computer simulation of an average atomic configuration.

The atomic model developed for the as-quenched structure which "fits" the first five experimental SRO coefficients shows that the local atomic arrangements consist of clusters of molybdenum atoms in the {100} planes. The atoms within the clusters satisy the long-range-ordered structure of Ni₄Mo since there are no Mo-Mo pairs as first neighbors, only one as second neighbors and six or more as third neighbors. The rodlike morphology of the molybdenum clusters grows on ordering for 5 minutes at 650°C. This result corroborates the rodlike morphology present in dilute Ni-W alloys and explains the [100] streaking observed in the diffraction studies.

CHAPTER I

INTRODUCTION

The order-disorder transformation in nickel-20 atomic percent molybdenum, Ni₄Mo, alloy has been the subject of considerable study for the past ten years (1-10). The transformation occurs at 868°C and undergoes a crystal structure change from the disordered face-centered cubic (fcc) to the ordered body-centered tetragonal (bct) phase (10). Both electron microscopy and x-ray diffraction have been used to characterize the kinetics and mechanism of the transformation (1-10).

Spruiell (3) performed a two-dimensional x-ray diffuse scattering measurement on the as-quenched alloy and constructed a model for the short-range order (SRO) structure present. He concluded that the SRO structure consisted of small regions in which the atomic arrangements are quite similar to the long-range ordered (LRO) Ni₄Mo structure. This description has lead to the "microdomain theory" for ordering in Ni₄Mo (8,9). The development of LRO is assumed to proceed by the growth of tiny ordered domains which are embedded in a random matrix. Ruedl et al (8) have claimed to observe such domains in dark-field electron micrographs. Consequently, the SRO diffuse peaks are considered as broad superlattice reflections and should occur at the same positions in reciprocal space as the superlattice peaks. However, they do not.

On the other hand, Clapp and Moss (11) from theoretical considerations of interaction potentials reproduced the diffuse intensity distribution obtained by Spruiell et al (3). They discount the microdomain concept for ordering in Ni₄Mo since their statistical thermodynamic model of SRO could describe the local order in the as-quenched alloy. Field-ion studies of LeFevre et al (4,7) have also failed to substantiate the presence of microdomains in Ni₄Mo.

Okamoto (5) has suggested a modification of the domain concept using the layered structure of LRO Ni₄Mo. He shows that as-quenched Ni₄Mo contains some form of ordered domains in all the six orientation variants of the Ni₄Mo structure, and suggests that the diffuse 140 peaks can be attributed to non-conservative antiphase boundaries within these microdomains. Okamoto (5) questions such a description for the disordered alloy since it would require the presence of superlattice reflections above the critical temperature, T_c! The problem lies in the fact that no complete description exists for the disordered alloy.

Warren (14) has shown that the pair probability function P_{lmn} can be obtained directly from the coefficients of the Fourier expansion of the diffuse x-ray intensity corresponding to local order in a binary alloy. If the intensity is known within its repeat volume, the pair probabilities are obtained uniquely by inverting the equation:

$$I_{SRO} = NX_A X_B (f_A - f_B)^2 \sum_{n} \sum_{n} \sum_{n} (1 - \frac{P_{1mn}^{BA}}{X_B}) \exp(i\vec{k} \cdot \vec{R}_{1mn})$$
[1]

where X_A and X_B are the atomic fractions of the species A and B having f_A and f_A as their respective atomic scattering factors. \vec{K} is the recipiodal lattice vector, $\frac{\vec{k}}{\lambda} = h_1b_1 + h_2b_2 + h_3b_3$ where $\vec{b}_1 = 2/a_1$. \vec{R}_{lmn} is the interatomic vector for the position defined by

coordinates 1,m,n, and N is the total number of atoms irradiated by the BA beam. (1- P_{lmn}/X_B) is the Warren short-range order parameter, α_{lmn} , where P_{lmn}^{BA} is the probability of finding a B atom in the lmm shell after having found the A atom at the origin. Thus if we measure the diffuse x-ray scattering corresponding to local order we can obtain an average atomic configuration for the structure under investigation.

The diffuse x-ray scattering measured contains contributions not only due to local order but also due to other factors. Most of these, such as Compton scattering, air scattering and flourescence of the alloy sample, can be corrected for by either theoretical or experimental methods. Contributions in the diffuse intensity due to first and second order thermal diffuse scattering (TDS), size-effect modulations, the Huang peak, have previously been separated by a theoretical analysis which introduced unavoidable assumptions regarding the nature of these effects. Recently, Borie and Sparks (16) proposed a theoretical method which allows one to correct for the above mentioned effects using the experimentally measured intensities. This allows the recovery of I_{SRO} unaffected by the size-effect contributions. Then, with the use of equation 1, the required pair probabilities for the determination of the average configuration of the as-quenched alloy can be obtained. A knowledge of the pair probability function PRA allows the simulation of an atomic configuration within a crystal lattice that satisfies the given pair probabilities. Such a method was first used by Gehlen and Cohen (12) and later by Williams (13).

Spruiell's et. al (3) data was two-dimensional and did not allow a unique determination of the pair probabilities. Therefore, their data

cannot be used for the simulation of the atomic configuration of the as-quenched alloy. Because of these uncertainties, a more exact description of the as-quenched alloy derived from three-dimensional data was felt worthwhile. The primary goal of this research was to use x-ray diffuse scattering and the 3D method of Borie and Sparks (15-17) to quantitatively study the state of local order, and follow the initial development of LRO in Ni₄Mo. The pair probabilities determined would then be applied to structure simulation so that a better understanding of short-range order and development of the long-range order might be possible.

CHAPTER II

THEORY

The theory pertaining to the x-ray diffuse scattering from binary has been very extensively reviewed (15) and reproduced in various dissertations (3,18-20), and will not be repeated here. The purpose of this section will be to summarize the theory and to introduce the necessary equations for the three dimensional separation method.

According to the kinematic theory of x-ray diffraction, the total coherent intensity in electron units is given by the formula

$$I_{eu} = \sum_{p \neq q} \sum_{p \neq q} f_{q} \exp \{i\vec{k} \cdot (\vec{R}_{o} - \vec{R}_{q})\}$$
 [2]

where f_p and f_q are the atomic scattering factors for the atoms located at sites p and q which are separated by the interatomic lattice vector $\vec{R}_p - \vec{R}_q$. In a real binary substitutional solid solution, the atom positions in the crystal lattice are often displaced from their nodal positions due to atomic size differences and thermal vibrations. If we include these static and dynamic displacements, the lattice vector becomes

$$(\vec{R}_p - \vec{R}_q) + (\vec{\delta}_p - \vec{\delta}_q)$$

where $\frac{1}{p}$ and $\frac{1}{q}$ represent the displacements from the nodal positions. Substituting this in equation 2 we obtain

$$I_{eu} = \sum_{p \neq q} \sum_{p \neq q} f_{p} \exp \left\{ i\vec{k} \cdot (\vec{k}_{p} - \vec{k}_{q}) \right\} \exp \left\{ i\vec{k} \cdot (\vec{b}_{p} - \vec{b}_{q}) \right\}$$
[3]

By expanding the second exponential to include second order terms, and introducing the concept of order through the Warren short-range order coefficient, α_{lmn} , Borie and Sparks (16) have shown that the total coherently scattered intensity can be written as

$$\begin{split} \mathbf{I}_{\mathbf{e}\mathbf{u}} &= \sum_{\mathbf{p}} \sum_{\mathbf{q}} \left(\mathbf{X}_{\mathbf{A}}^{\mathbf{f}}_{\mathbf{A}} + \mathbf{X}_{\mathbf{B}}^{\mathbf{f}}_{\mathbf{B}} \right)^{2} \, \exp \, \langle i\vec{\mathbf{k}} \cdot \vec{\mathbf{k}}_{\mathbf{p}\mathbf{q}} \rangle \\ &+ \sum_{\mathbf{p}} \sum_{\mathbf{q}} \left(\mathbf{X}_{\mathbf{A}}^{\mathbf{q}} + \mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} \right)^{2} \, \alpha_{\mathbf{p}\mathbf{q}} \, \exp \, \langle i\vec{\mathbf{k}} \cdot \vec{\mathbf{k}}_{\mathbf{p}\mathbf{q}} \rangle \\ &+ \sum_{\mathbf{p}} \sum_{\mathbf{q}} \left\{ \left(\mathbf{X}_{\mathbf{A}}^{\mathbf{q}} + \mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} \right)^{2} \, f_{\mathbf{A}}^{\mathbf{q}} \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{A}}) \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} \mathbf{f}_{\mathbf{B}} (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \rangle \\ &+ \left(\mathbf{X}_{\mathbf{B}}^{2} + \mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} \alpha_{\mathbf{p}\mathbf{q}} \right) \, f_{\mathbf{B}}^{2} \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{B}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \rangle \, \exp \langle i\vec{\mathbf{k}} \cdot \vec{\mathbf{k}}_{\mathbf{p}\mathbf{q}} \rangle \\ &- \frac{1}{2} \sum_{\mathbf{p}} \sum_{\mathbf{q}} \left\{ \left(\mathbf{X}_{\mathbf{A}}^{2} + \mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} \alpha_{\mathbf{p}\mathbf{q}} \right) \, f_{\mathbf{A}}^{2} \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \right\} \, \exp \langle i\vec{\mathbf{k}} \cdot \vec{\mathbf{k}}_{\mathbf{p}\mathbf{q}} \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} f_{\mathbf{A}}^{\mathbf{f}}_{\mathbf{B}} \, (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \rangle \, \exp \langle i\vec{\mathbf{k}} \cdot \vec{\mathbf{k}}_{\mathbf{p}\mathbf{q}} \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} f_{\mathbf{A}}^{\mathbf{f}}_{\mathbf{B}} \, (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \right]^{2} \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} f_{\mathbf{A}}^{\mathbf{f}}_{\mathbf{B}} \, (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \right]^{2} \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} f_{\mathbf{A}}^{\mathbf{f}}_{\mathbf{B}} \, (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \right]^{2} \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} f_{\mathbf{A}}^{\mathbf{f}}_{\mathbf{B}} \, (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \right]^{2} \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} f_{\mathbf{A}}^{\mathbf{f}}_{\mathbf{B}} \, (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \right]^{2} \rangle \\ &+ 2\mathbf{X}_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} f_{\mathbf{A}}^{\mathbf{q}}_{\mathbf{B}} \, (1 - \alpha_{\mathbf{p}\mathbf{q}}) \, \langle i\vec{\mathbf{k}} \cdot (\vec{\mathbf{d}}_{\mathbf{p}}^{\mathbf{A}} - \vec{\mathbf{d}}_{\mathbf{q}}^{\mathbf{B}}) \right]^{2} \rangle$$

where α is the Warren short-range order parameter.

The first sum of equation 4 is the intensity of the fundamental reflections unaffected by local order or static and dynamic displacements. The second sum is the Laue monotonic intensity modulated by the order parameter, α_{pq} . The third sum is the "size effect" or static displacement modulated intensity since $i\vec{K}(\vec{\delta}_p - \vec{\delta}_q) = 0$ for thermal motion using a harmonic oscillator model. Effects due to both thermal and static distortion are contained in the fourth sum. These include the first order temperature diffuse scattering and the Huang intensity. When this fourth sum is examined for convergence, it is found that a negative delta function is produced which peaks at the fundamental reflection positions. Physically this means that the mean square atomic displacements, which are acting cooperatively over long distances in the crystal, reduce the intensity of the fundamental reflections. The intensity lost by the fundamental reflections is redistributed as Huang and TDS. Thus if the limiting value of the mean square displacement is added to the first sum and subtracted from the fourth sum (when expressed in terms of a set of correlated displacement parameters), the intensity expression is immediately separable into two parts. One part represents the sharp crystalline reflections which are reduced in intensity for the reason just cited, and the other describes the diffuse intensity.

These are:

$$I_{\text{Fund}} = \sum_{\mathbf{p}} \sum_{\mathbf{q}} (X_{\mathbf{A}}^{\mathbf{f}} \mathbf{A}^{\mathbf{e}^{-\mathbf{M}_{\mathbf{A}}}} + X_{\mathbf{B}}^{\mathbf{f}} \mathbf{B}^{\mathbf{e}^{-\mathbf{M}_{\mathbf{B}}}})^{2} \exp \langle i \vec{\mathbf{k}} \cdot \vec{\mathbf{R}}_{\mathbf{p}\mathbf{q}} \rangle$$
 [5]

which is just like the fundamental reflection reduced in intensity by

the factor e M for each atom; and

$$I_{Diffuse} = \sum_{p \neq q} \sum_{A_{A}} X_{A_{B}} (f_{A} - f_{B})^{2} \alpha_{pq} \exp(-i\vec{k} \cdot \vec{k}_{pq})$$

$$+ \sum_{p \neq q} \sum_{A_{A}} X_{A_{B}} (f_{A} - f_{B}) = (\frac{X_{A}}{X_{B}} + \alpha_{pq}) f_{A} < i\vec{k} (\vec{\delta}_{p}^{A} - \vec{\delta}_{q}^{A}) >$$

$$- (\frac{X_{B}}{X_{A}} + \alpha_{pq}) f_{B} < i\vec{k} (\vec{\delta}_{p}^{B} - \vec{\delta}_{q}^{B}) > \exp(-i\vec{k} \cdot \vec{k}_{pq}) >$$

$$- \sum_{p \neq q} \sum_{A_{A}} (X_{A_{B}} (f_{A} - f_{B})) = ((X_{A} + X_{B} \alpha_{pq}) f_{A} < (\vec{k} \cdot \vec{\delta}_{p}^{A})^{2} > \frac{A}{q}$$

$$- X_{A} (1 - \alpha_{pq}) f_{A} < (\vec{k} \cdot \vec{\delta}_{p}^{A})^{2} > \frac{B}{q} + X_{B} (1 - \alpha_{pq}) f_{B} < (\vec{k} \cdot \vec{\delta}_{p}^{B})^{2} > \frac{A}{q}$$

$$- (X_{B} + X_{A} \alpha_{pq}) f_{B} < (\vec{k} \cdot \vec{\delta}_{p}^{B})^{2} > \frac{B}{q}$$

$$- X_{A} f_{A}^{2} (X_{A} + X_{B} \alpha_{pq}) < (\vec{k} \cdot \vec{\delta}_{p}^{A}) (\vec{k} \cdot \vec{\delta}_{q}^{A}) >$$

$$- X_{B} f_{A}^{2} (X_{B} + X_{A} \alpha_{pq}) < (\vec{k} \cdot \vec{\delta}_{p}^{A}) (\vec{k} \cdot \vec{\delta}_{q}^{A}) >$$

$$- X_{B} f_{B}^{2} (X_{B} + X_{A} \alpha_{pq}) < (\vec{k} \cdot \vec{\delta}_{p}^{A}) (\vec{k} \cdot \vec{\delta}_{q}^{A}) >$$

$$- X_{B} f_{B}^{2} (X_{B} + X_{A} \alpha_{pq}) < (\vec{k} \cdot \vec{\delta}_{p}^{A}) (\vec{k} \cdot \vec{\delta}_{q}^{A}) >$$

$$= (6)$$

The above equations are completely general to the second order approximation for the displacement effects and may be used for any crystal structure containing two atomic species. For face-centered and body-centered cubic substitutional solid solutions, $i\vec{k} \cdot \vec{k}_{pq} = 2\pi i (h_1 l_1 + h_2 m_2 + h_3 n_3)$ since $\vec{k} = 2\pi (h_1 b_1 + h_2 b_2 + h_3 b_3)$ and $\vec{k}_{pq} = 2\pi i (h_1 l_2 + h_3 l_3)$

 $la_1/2 + ma_2/2 + na_3/2$. h_1 , h_2 and h_3 are continuous variables in reciprocal space. Equation 6 reduces to (17)

$$I_{\text{Diffuse}} = NX_{\text{A}}X_{\text{B}}(f_{\text{A}} - f_{\text{B}})^{2} \sum_{\substack{1 \text{ m n} \\ 1 \text{ m n}}} \sum_{\substack{n \text{ m n} \\ 1 \text{ m n}}} \alpha_{\text{lmn}} (\cos 2\pi h_{1})(\cos 2\pi h_{2}^{\text{m}})(\cos 2\pi h_{3}^{\text{m}})$$

$$- NX_{\text{A}}X_{\text{B}}(f_{\text{A}} - f_{\text{B}})^{2} \sum_{\substack{1 \text{ m n} \\ 1 \text{ m n}}} \sum_{\substack{n \text{ m n} \\ 1 \text{ m n}}} \{h_{1}Y_{\text{lmn}}^{1} (\sin 2\pi h_{1})(\cos 2\pi h_{2}^{\text{m}})(\cos 2\pi h_{3}^{\text{m}})$$

$$+ h_{2}Y_{\text{lmn}}^{\text{m}} (\cos 2\pi h_{1})(\sin 2\pi h_{2}^{\text{m}})$$

 $(\cos 2\pi h_3 n)$

$$+ h_3 \gamma_{1mn}^n (\cos 2\pi h_1^1) (\cos 2\pi h_2^m)$$

(sin 2πh₃n)}

$$-4\pi^{2} N \sum_{1 \text{ m n}} (h_{1}^{2} < \delta^{2} > 1 + h_{2}^{2} < \delta^{2} > m + h_{3}^{2} < \delta^{2} > 1 + h_{2}^{2}$$

 $x \{(\cos 2\pi h_1 1)(\cos 2\pi h_2 m)(\cos 2\pi h_3 n)\}$

+
$$8\pi^2 N \Sigma \Sigma \Sigma \{h_1h_2 < \delta^2 > \frac{1m}{mn} (\sin 2\pi h_1 1) (\sin 2\pi h_2 m) (\cos 2\pi h_3 n)$$

$$+ h_1 h_3 < \frac{3}{2} > \frac{\ln}{1 m n} (\sin 2\pi h_1 l) (\cos 2\pi h_2 m) (\sin 2\pi h_3 n)$$

+
$$h_2h_3 < 3^2 > mn (\cos 2\pi h_1 1) (\sin 2\pi h_2 m) (\sin 2\pi h_3 n)$$

with all sums extending from -N to N.

Here

$$\gamma^{1} = \frac{2\pi}{f_{A} - f_{B}} \left[(X_{B}^{X} + \alpha_{1mn}) f_{A} (X^{AA}) \right]_{nmn} - (X_{B}^{B} + \alpha_{1mn}) f_{B} (X^{BB})_{nmn} \right] [7.1]$$

$$\langle \delta^{2} \rangle_{1mn}^{1} = X_{A} X_{B} (f_{A} - f_{B}) \left[(X_{A} + X_{B} \alpha_{1mn}) f_{A} (X^{A})^{2} \rangle_{1mn}^{A} - X_{A} (1 - \alpha_{1mn}) f_{A} (X^{A})^{2} \rangle_{1mn}^{B}$$

$$+ X_{B} (1 - \alpha_{1mn}) f_{B} (X^{B})^{2} \rangle_{1mn}^{A} - (X_{B} + X_{A} \alpha_{1mn}) f_{B} (X_{B})^{2} \rangle_{1mn}^{B}$$

$$- X_{A} (X_{A} + X_{B} \alpha_{1mn}) f_{A}^{2} (X^{A} X^{A})_{1mn} - 2X_{A} X_{B} (1 - \alpha_{1mn}) f_{A} f_{B} (X^{A} X^{B})$$

$$- X_{B} (X_{B} + X_{A} \alpha_{1mn}) f_{B}^{2} (X^{B} X^{B}) \qquad [7.2]$$

$$- X_{B} (X_{B} + X_{A} \alpha_{1mn}) f_{A}^{2} (X^{A} Y^{A}) - 2X_{A} X_{B} (1 - \alpha_{1mn}) f_{A} (X^{A} Y^{B})$$

$$- X_{B} (X_{B} + X_{B} \alpha_{1mn}) f_{A} (X_{B} Y^{A}) - 2X_{B} (X_{B} Y^{A})$$

The equation is based on the following assumptions:

- (i) The magnitude of the displacements is sufficiently small to be adequately described by first and second order terms;
- (ii) The ratio of the atomic scattering factors, f / f_B is constant over the reciprocal space volume in which the measurements are made.

The coefficients of each sum may be recovered since each has a different dependence on h_1 , h_2 and h_3 .

Following Borie and Sparks (16) we define our operator A as,

T1H2 =
$$\Delta(h_2-1)I(h_1,h_2,h_3) = I(h_1,h_2,h_3) - I(h_1,h_2-1,h_3)$$

= $-NX_{AB}(f_Af_B)^2 \sum_{l m n} \sum_{l m n} \gamma_{lmn}^m (\cos 2\pi h_1 l) (\sin 2\pi h_2 m) (\cos 2\pi h_3 n)$
+ $4\pi^2 N \sum_{l m n} \sum_{l m n} (1-2h_2) < \delta^2 > m_{lmn} (\cos 2\pi h_1 l) (\cos 2\pi h_2 m) (\cos 2\pi h_3 n)$
+ $8\pi^2 N \sum_{l m n} \sum_{l m n} \{h_1 < \delta^2 > l_{lmn}^m (\sin 2\pi h_1 l) (\sin 2\pi h_2 m) (\cos 2\pi h_3 n)$
+ $h_3 < \delta^2 > m_{lmn} (\cos 2\pi h_1 l) (\sin 2\pi h_2 m) (\sin 2\pi h_3 n) \}$

With reference to Figure la, the difference in intensity on subtracting point B from A is the Δ operation. If this operation is performed over the whole volume, the function represented by Equation 8 will be known in the volume shown in Figure 1b. The difference operator, T2H2, is obtained by performing the same operation on the volume shown in Figure 1b.

$$T2H2 = \Delta^{2}(h_{2}-1)I(h_{1},h_{2},h_{3}) = \Delta(h_{2}-1)I(h_{1},h_{2},h_{3}) - \Delta(h_{2}-1)I(h_{1},h_{2}-1,h_{3})$$

$$= -8\pi^{2}N \sum_{l = 0}^{\infty} \sum_{l = 0}^{\infty} (\cos 2\pi h_{1}l)(\cos 2\pi h_{2}m)(\cos 2\pi h_{3}n)$$
[9]

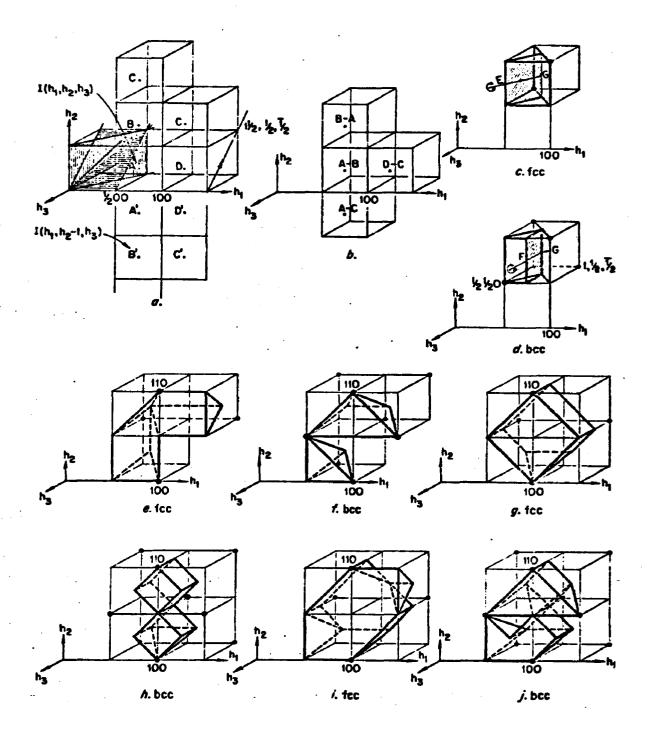

Figure 1. The Regions of Reciprocal Space for Making Volume Measurements of Diffuse Scattering for the Cubic Systems. (a) Δ(h₂-1) operation in the volume. (b) Volume obtained after Δ(h₂-1) separation. (c)(d) Minimum repeat volume for the term < 3²/_{lumn} for the fcc and bcc, respectively. (e)(f) Volume of diffuse intensity data necessary to obtain the < 3²/_{lumn} term for fcc and bcc systems, respectively. (g)(h) Volume of diffuse intensity data necessary to obtain the < 3²/_{lumn} term for the fcc and bcc systems, respectively. (i)(j) Volumes of diffuse intensity data necessary to perform the quadratic separation method for the fcc and bcc systems, respectively. Sparks (17)

Having recovered the function given in Equation 9, the other two functions containing $<3^2>_{lmn}^1$ and $<3^2>_{lmn}^n$ can be generated by interchanging the indices h_1 with h_2 and h_2 with h_3 , respectively, since the alloy is statistically cubic. Sparks (17) has shown that the function represented by equation 9 is defined everywhere in reciprocal space if it is known in the volumes shown in Figures 1c or 1d for the fcc or bcc structures, respectively. Aplane containing the symmetry axis 'fg' cuts the volume in half leaving the choice of the repeat volume rather flexible. The size and shape of this repeat volume is the same as that for the function γ_{lmn}^m . Figure 1e and 1f shows the volume of diffuse intensity data necessary to obtain the minimum repeat volume for the function $<3^2>_{lmn}^m$ for face-centered and body-centered cubic structures respectively.

By performing the operation $\Delta(2-h_1)$ on equation 8 we have the result that

$$T1H1 = \Delta(2-h_1)\Delta(h_2-1)I(h_1,h_2,h_3) = \Delta(h_2-1)I(h_1,h_2,h_3) - \Delta(h_2-1)I(2-h_1,h_2,h_3)$$

=
$$16\pi^2 N \sum_{l m n} \sum_{m n} (\sin 2\pi h_1 l) (\sin 2\pi h_2 m) (\cos 2\pi h_3 n)$$
 [10]

The volume of diffuse intensity data needed to do this separation is shown in Figure 1g where the intensity (D-C) is subtracted from the intensity (A-B) for the fcc structure and Figure 1h for the bcc structure. The other two functions containing $<3^2>_{1m}^{1n}$ and $<3^2>_{1m}^{mn}$ can be generated from the recovered function of equation 10 by interchanging h_3 for h_2 and h_3 for h_1 , respectively.

The function $\sum \sum \gamma_{lmn}^{m} (\cos 2\pi h_1 l) (\sin 2\pi h_2 m) (\cos 2\pi h_3 n) \cos now 1 m n$

be recovered from the intensity distribution represented by equation 8, since the value of the latter two sums is known. Likewise it is straightforward to recover the remaining function $\sum_{n=1}^{\infty} \sum_{n=1}^{\infty} \alpha_{n} (\cos 2\pi h_{n}) (\cos 2\pi h_{n})$ (cos $2\pi h_{n}$) from equation 7 since all the other terms are known.

One of the many possible volumes in reciprocal space in which the measured intensity distribution is sufficient to allow a complete separation of the four different kinds of terms given in equation 7 is made by combining the volumes of Figure 1e and 1g or Figure 1f and 1h for the fcc and bcc cases, respectively. These volumes are shown in Figure 1i and 1j for fcc and bcc respectively.

The three dimensional analysis of Borie and Sparks (16) described in this Chapter allows a determination of the coefficients α_{lmn} , γ_{lmn}^m , 2 , m , 2 , lm . With these coefficients, a probable atomic configuration of the alloy can be computer simulated using the method of Williams (13).

CHAPTER III

EXPERIMENTAL METHODS

The method just described requires that the total diffuse scattered intensity be measured over the volume of reciprocal space shown in Figure 1i, using a single crystal sample. The Ni₄Mo single crystal was supplied by Dr. J. E. Spruiell of the University of Tennessee. The single crystal was oriented to have the (210) planes parallel to the surface; an orientation which allows maximum accessibility to the region of principal interest in reciprocal space.

The measurements of the total diffuse scattered intensity were made utilizing a four-circle goniometer described elsewhere (23). This completely automated unit was driven by a Datex unit which reads instructions from a paper tape. The diffractometer was aligned and a (111) oriented silicon single crystal was used to determine the true zero in 2.0. The horizontal and vertical divergences of the slit system was 1.5 and 3.0 degrees respectively. The incident beam from the copper tube (34KV, 14ma) was monochromated using a doubly-bent pyrolytic graphite monochromator. The half-wavelength as well as the higher order harmonics that pass the monochromator were removed using balanced filters in the incident beam. This procedure removes the occurrence of fluorescence from the sample which would otherwise add to the total measured diffuse scattering. The single crystal was carefully aligned

^{*} Very kindly loaned to us by Dr. C. J. Sparks of Oak Ridge National Laboratory.

and the true zero's of 20, 0, x found and set. The sample was placed in a helium gas chamber to reduce air scattering. A scatter slit placed between the sample chamber and the detector prohibited the radiation scattered by the chamber walls from entering the detector.

The measurements of the total diffuse scattering intensity were made over 6 planes along the h_3 direction, and represented a set of 1576 points on a square grid in reciprocal space spread uniformly over the volume of Figure 1i at intervals of $\Delta h_1 = 0.05$ in the reciprocal lattice. Based on the initial orientation of the single crystal, the χ , \emptyset and 20 setting for each of these points was computed by the program MFVOL (listed in the appendix) and these settings converted to Datex instructions and punched onto a paper tape. A check point was programmed in the tape, so that after every 50 data points, this check point would be read in order to monitor any power fluctuations of the primary beam. Corrections due to the fluctuations were made by normalizing the data with respect to the check point.

The conversion of the measured diffuse scattered intensity to absolute electron scattering units was made by measuring the amorphous scattering from polystrene (\S^H_8) at 100 degrees 2.9 and using the physical constants in Table 1. This intensity was then corrected for polarization factor, resonance x-rays (25) and Compton scattering and finally divided by the Laue Monotonic intensity. The atomic scattering factors used were corrected for dispersion effects. The Compton scattering intensity was computed from values of the incoherent scattering

^{*} The value of the nickel resonance was measured by Dr. C. J. Sparks of Oak Ridge National Laboratory.

 $\frac{1}{\rho}$ = 65.00

function given by Compton and Allison (24). The various corrections were performed by the program INTCOR, written for such work. The resulting intensity represented the diffuse intensity modulated by local order, size effects, and thermal diffuse scattering.

The separation, as described in Chapter II, of the various components of the diffuse intensity is performed by program SEPRIT, written to do the three dimensional separation for the quadratic approximation The output of this program gives us the various intensity components in their respective repeat volumes for recovering the coefficients, α_{lmn} , γ_{lmn}^m , $\langle \delta^2 \rangle_{lmn}^m$, $\langle \delta^2 \rangle_{lmn}^{lm}$ by Fourier inverting their appropriate intensities, which is performed by program COEFFS. All of these programs are listed in the appendix. Since fundamental peaks are present in the volume in which the diffuse scattering is measured, they appear after the separation in the local-order component. Thus, before the alphas can be computed the fundamental intensities present have to be This was accomplished by assuming that the short range order intensity vanishes at the Bragg positions and extrapolating the shortrange order intensity smoothly through these regions. The short range order coefficients thus obtained is finally used in the Williams (13) program to simulate the atomic configuration present in the disordered, and after 5 and 10 minutes ageing at 650°C.

The Williams (13) program uses 8000 atoms for the simulation and the composition of the alloy fixes the number of 1's (X_A) and 0's (X_B) present in the entire model. These atoms are interchanged until the alphas calculated for each site move towards the desired value, i.e. the experimentally observed values. This is done by examining individual

sites and not changing any site which would cause the composition to fall outside prescribed limits. Provided this criterion is met, a site is changed if the vector sum of the alphas moves closer to the design value. This program differs from Gehlen and Cohen's (12) program in the manner in which it examines the sites. The pairs to be interchanged are selected at random in Gehlen and Cohen's program, while Williams' developed a method of scanning which allows the entire model to be scanned sequentially in such a manner that the neighbors of any given site are examined in a random fashion. This scheme is faster and insures that each site is examined. The input data for Williams' program are the first three alphas, the overall composition of the alloy and the range within which the composition is allowed to vary. Once the model has been generated in the computer, any predetermined number of alphas may be calculated and printed. The resulting atomic configurations on successive (100) planes of the model are then printed out.

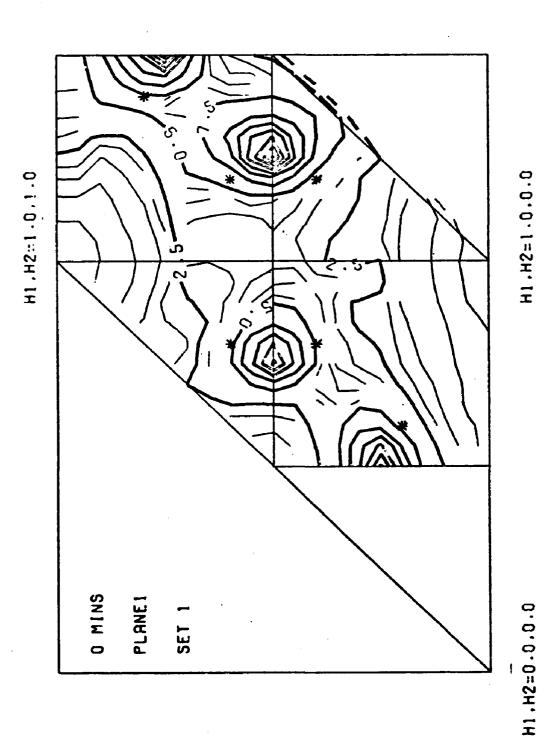

CHAPTER IV

RESULTS AND DISCUSSION

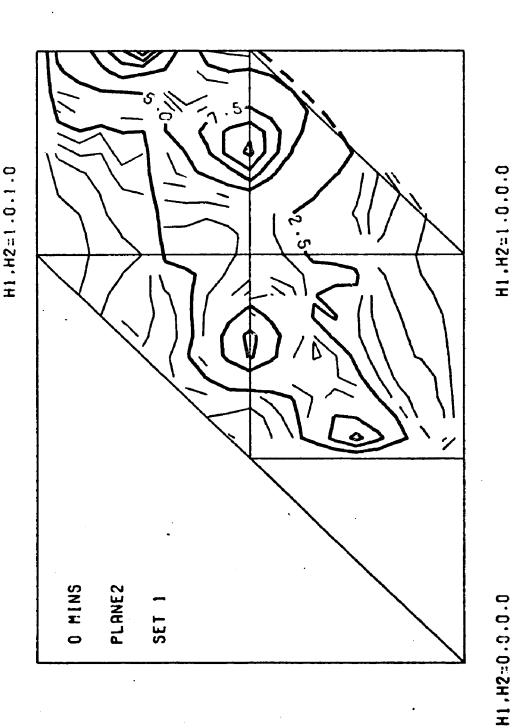

The measured diffuse intensity for the as-quenched alloy is shown in Figure 2a-f for the six planes in the fcc volume. The intensities are in Laue Monotonic units having been previously corrected for Compton scattering and nickel resonance x-rays (25). The diffuse peaks occur at $(1,\frac{1}{2},0)$ and their equivalent positions in reciprocal space. The contours show that the peaks are very broad and spread over a large volume in reciprocal space with tails extending approximately 10 degrees on either side of the peak. The peaks are not very symmetrical due to the size effect intensity. The intensity distribution for plane 1 is similar to that obtained by Spruiell et al (3).

The superlattice reflections of Ni₄Mo occur at positions different than the diffuse peaks. These positions are shown by astericks on Figure 2a and 3a. The diffuse scattering contours do not appear to be affected by any intensity at the superlattice peak positions.

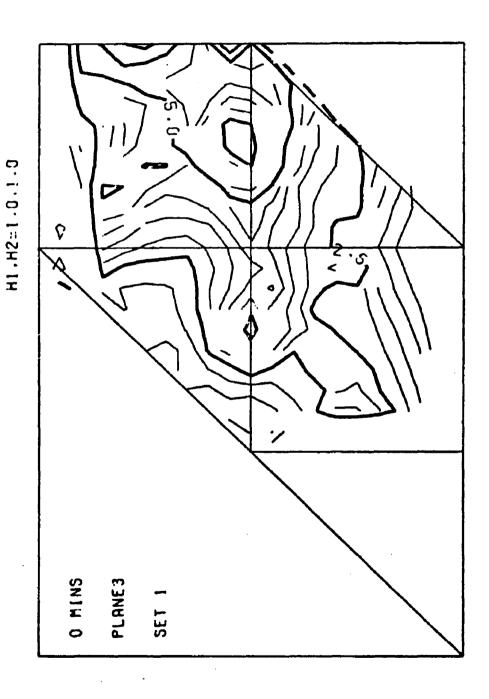

Okamoto (5) studied as-quenched Ni₄Mo using electron diffraction techniques. He plotted the diffracted intensity obtained along the [420] direction on (121) planes and observed small intensity maxima at superlattice peak positions. He claims this as evidence for ordered domains existing in the as-quenched alloy. Since the volume in which our measurements were made does not include a large section of the (121) plane, this could not be checked throughly. Instead, the intensity distribution along the [420] direction on the (100) plane is shown in Figure 4.

Although the (100) planes are not the most suitable for observation of superlattice intensities, it can be seen that small maxima do occur at superlattice peak positions, and these maxima are simply due to the diffuse peak tails. These are not due to any other intensities as can be seen from the 3D map of Figure 5.

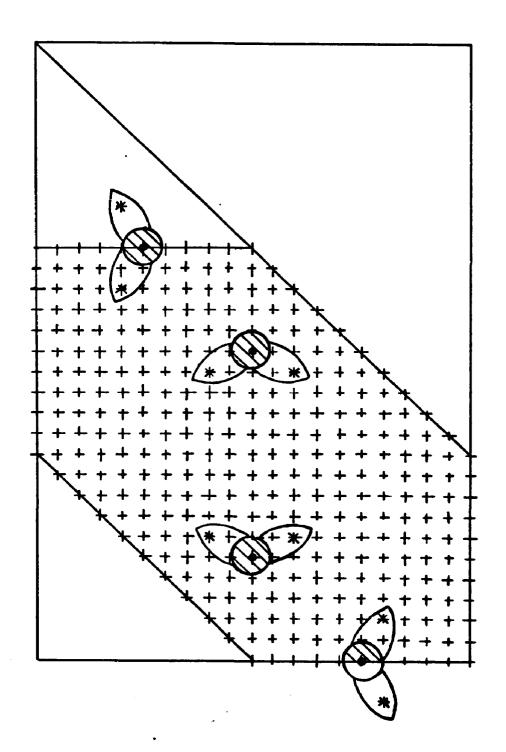

On ordering the alloy for 5 minutes at 650°C, the diffuse peaks sharpen considerably and the peak intensity increases by approximately threefold, Figure 3a-f. It is interesting to compare the (002) electron diffraction pattern, Figure 6b, of reference 5 and our Figure 3a, since they are supposed to represent the same state of order (heat treated ... for 5 minutes at 650°C). The diffuse intensity distribution present in the electron diffraction pattern of reference 5 is shown schematically in Figure 6, where each diffuse spot is related to its superlattice peak by a "paddle shaped" intensity distribution. An examination of Figure 3a where the superlattice peak positions are marked by astericks shows no clear cut "paddle shaped" intensity. Since the manner by which the ordering was performed was different (in our case, the sample was encapsulated in a quartz tube under vacuum and heated in a furnace, whereas Okamoto heat-treated small disc-like samples in a salt bath at 650°C). the state of order considered might be different. The intensity distribution of Figure 6b of reference 5 shows a stage of ordering far advanced, whereas Figure 3a shows an earlier stage. The intensity distribution obtained for the sample ordered 10 minutes at 650°C is similar to the 5 minutes ordered case, except that the peak intensities are slightly higher. Plots of the measured diffuse intensity for the 10 minutes ordered sample are given in the appendix.

A Schematic of the Intensity Distribution on the (200) Plane of Nigho as Shown by reference (5). (Astericks marks positions of superlattice peaks). Figure 6.

The measured intensities were separated into the different components using the program SEPRIT, which gives the separated components in their respective repeat volumes. The short range order intensity obtained after separation of the "size effect" for the as-quenched alloy is shown in Figure 7a-f. The intensity distribution is symmetrical about the diffuse peak positions. The coefficients, $\alpha_{\rm lmn}$, $\gamma_{\rm lmn}^{\rm m}$, $\Leftrightarrow^2>_{\rm lmn}^{\rm m}$, $\Leftrightarrow^2>_{\rm lmn}^{\rm m}$, are obtained by Fourier inversion using the repeat volumes and their respective summetries for the different components. The δ coefficients represent the combined first order TDS and second order static displacement terms. These coefficients, for the as-quenched and slightly-ordered cases, have been added in the appendix. These coefficients decrease with increasing order.

Table 2 gives the three-dimensional local order parameters obtained from the separated short-range order component for the three different cases. The coefficients were checked by synthesizing the local-order intensities and recalculating the alphas from the synthesized intensity. The round off error was less than one percent. Since the ordered peaks were fairly sharp, alphas up to (888) were used to synthesize the intensity. α_{000} = 1.587 for the as-quenched alloy although theoretically the value should be 1.000. A disagreement of this magnitude is common in the literature on diffuse scattering measurements, although the reason is unclear. Gragg (20) has shown from theoretical error analysis that about 20 percent of the error in α_{000} can be attributed to the noninclusion of displacement effect terms higher than second order. The extra unaccountable intensity might arise from resonance x-rays (25) and affects the lower order coefficients the most.

The SRO coefficients obtained were used to computer simulate an average atomic configuration for the alloy. Performing such a simulation with Williams (13) program for the as-quenched and 5 minutes ordered structure a model was obtained from which the SRO coefficients could be calculated. A comparison of the alphas obtained from the model and those measured is shown in Table 3 for the as-quenched and 5 minutes ordered alloy. The fit extends down to the higher order alphas and is consistent with the measured values in signs and magnitude. The model developed follows the large rise in α_{200} , observed experimentally when the alloy was ordered slightly. In addition to generating the model and giving the relative positions of the two kinds of atoms in the model, the computer may be programmed to search the model for atoms or groups of atoms satisfying certain specified criteria. This information produces a better insight and understanding of the model. Tables 4-5 give some information of this type for the as-quenched alloy. Table 4 gives the number of molybdenum neighbors in the first and second shell for each Mo atom in a random alloy. Table 5 lists similar information for the model of the as-quenched alloy. There are 23 molybdenum atoms having no first Mo neighbors and 2 second nearest Mo neighbors in the random alloy, while this number increases to 279 for the as-quenched alloy. Physically this means that "clusters" form.

To obtain a better concept of the local order it is useful to try to isolate regions in the model which meets a specified criterion and to examine the size and shape of such regions. Various authors (3,5,8,9) have argued that the as-quenched condition in Ni₄Mo consists of microdomains of LRO, so this possibility was examined. Each

molybdenum atom was examined using a criteria based on the long-range ordered structure; i.e., no molybdenum-molybdenum first neighbors and only one Mo-Mo second nearest neighbors. Generally a criterion based on the first and second shells is sufficient to isolate the regions, but as will be seen on examining Figures 8 and 9, this is not sufficient for Ni, Mo. The third shell has to be considered before a structure of the clusters can be established. Figures 8 and 9 show five consecutive (100) planes of the computer model for the as-quenched and 5 minutes ordered sample. The symbol 1 represents molybdenum and 0 the nickel Each plane contains 200 atoms of the total 4000 atoms in the The criterion used to mark out the areas was using a Mo atom as the origin, no Mo atoms in the first shell, one or more in the second shell and six or more in the third shell. This criteria closely approximates the model developed by Spruiell (3). The boundary lines drawn show small areas in which the criterion was satisfied. The areas are four to six atoms diameter in size, or approximately 15 to 20 A. This is indeed the size of the microdomains that have claimed to exist in this alloy (3,9). This size of the domains does not change much on ordering for 5 minutes at 650°C, but the order is more complete as seen in Figure 9. An attempt was made to see if the composition fluctuations mentioned by Okamoto (5) could be observed in these computer maps. This failed since the areas mentioned are so small that a sufficient number of (420) planes were not found.

Streaks of intensity along the [100] directions are observed at the peak positions of the diffuse intensity distributions shown in

Figure 9. Atomic Arrangements of Computer Generated Model for Alloy Aged for 5 Minutes at 650°C.

Figures 2 and 3. The streaks get more prominent on ordering at 650°C and are accompanied by a large rise in the value of α_{200} , from -0.010 to 0.112 (Table 2). This feature was reproduced in the short-range coefficients obtained from the simulated model (Table 3). Thus it is to be expected that the computer maps would show this feature and indeed they do. Figure 10, for as-quenched alloy shows that the atomic configuration consists of rods on (200) planes lying in <100> directions. About 55 percent of the molybdenum atoms in the model are in the rods. As the alloy orders the rods get longer as seen in Figure 11 for the 5 minutes ordered case. Here about 63 percent of the molybdenum atoms are in the rods configuration. The morphology described here, although never before discussed for Ni, Mo, has been suggested for nickel-10 atomic percent tungsten alloy (26). The nickel-tungsten system is very similar to the nickel-molybdenum system and Ni_LW is structurally the same as Ni_LMo (28). Okamoto shows photographs of microdomains in Ni2Mo ordered for 10 minutes at 750°C and claims that the microdomains are equiaxed and have a size distribution of 20 to 100 A. However, close examination of Figure 10b in reference 5 shows those microdomains as small rods. Okamoto also claims that "there is a slight tendency for the domains of a particular variant to align themselves in rows was observed with longer ageing times but neither with sufficient frequency nor with sufficient directional uniqueness to establish any definite relationship with a diffraction effect." The field-ion (5) micrographs also show clusters of molybdenum atom in a rod-like fashion. We conclude that the as-quenched structure of Ni_4 Mo has rod-like clusters of molybdenum atoms which satisfy the primary characteristic of Ni Mo, in that there are no Mo-Mo first

nearest neighbors. This morphology also explains the unusual rise in $lpha_{200}$ and the [100] streaking observed in the diffuse scattering maps.

CHAPTER V

CONCLUSIONS AND RECOMMENDATIONS

Conclusions

The three-dimenional diffuse scattering measurements have been analyzed for the as-quenched Ni₄Mo and show that the structure in the quenched state has tiny rodlike regions. These rods:

- i) satisfy the primary requirement of the LRO structure in that there are no molybdenum-molybdenum neighbors in the first shell;
 - ii) grow on ordering:
- iii) satisfies the measured alpha parameters and explain the streaks of intensity observed in the measured diffuse scattering.

Recommendations

The local order coefficients obtained from this study can be used for the following calculations and modeling which will aid in a general understanding of solid solutions:

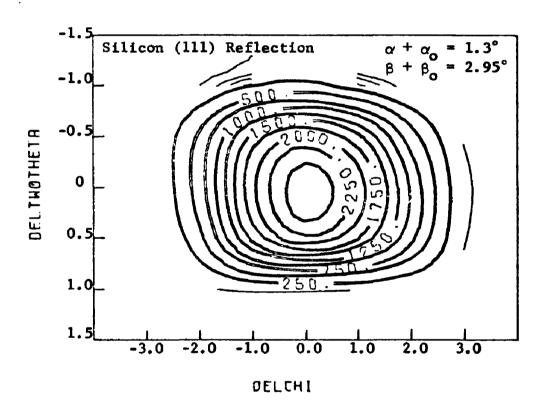

(i) The alphas can be used to test the validity of the quasichemical approach to solid solutions. The quasi-chemical theory maintains that the energy of a solution is given by the sum of constant
pairwise interaction energies between the various neighbors and that
volume and vibrational changes accompanying the formation of the alloy
from its components can be neglected. We may use the short-range order
coefficients to extract the interaction energies from a set of simultaneous equations, provided sufficient coefficients are available.

Using these interaction energies the validity of Clapp and Moss's (11) theory, i.e., that the disordered state above T_c is best described by a "liquid-like" structure or a statistical model of \$0, can be checked.

- (ii) The short-range order coefficients can be used to calculate thermodynamics data, e.g., $\Delta H_{configurational} = NX X_B \Sigma C_{1}\alpha_1 V_1$ and the calculated value be compared with that obtained from specific heat data.
- (iii) The alphas can be used to predict configurational changes, and therefore the strength, of Ni Mo due to deformation.
- (iv) Finally, an analysis of the static displacement coefficients determined from the diffuse scattering experiments can be made in order to clarify the elastic properties of Ni_AMo.

VITA

Name: Bhaven Chakravarti

Date of Birth: January 4, 1945

Place of Birth: Patna, Bihar, India

Education:

Indian Institute of Technology Bachelor of Technology May, 67 Kharagpur, India in Met. Engineering

Georgia Institute of Technology Master of Science June, '70 Atlanta, Georgia in Metallurgy

Married: February 15, 1970

Wife: Nandita Chakravarti

Children: Anita Chakravarti, born June 15, 1973, Atlanta, Georgia

Member: Sigma Xi, American Society for Metals, American Institute of Mining, Metallurgical, and Petroleum Engineers

Publications:

B. Chakravarti, E. A. Starke, B. G. LeFevre, "Order Induced Strengthening in Ni₄Mo", Journal of Material Science, <u>5</u>, 1970, p. 394.
